Abstract

A novel treatment of non-adiabatic couplings is proposed. The derivation starts from the long-known, but not well-known, fact that the wave function of the complete system of electrons and nuclei can be written, without approximation, as a Born-Oppenheimer-type product of a nuclear wavefunction, $X(R)$, and an electronic one, $\Phi_R(r)$, which depends parametrically on the nuclear configuration R . From the variational principle we deduce formally exact equations for $\Phi_R(r)$ and $X(R)$. The algebraic structure of the exact nuclear equation coincides with the corresponding one in the adiabatic approximation. The electronic equation, however, contains terms not appearing in the adiabatic case, which couple the electronic and the nuclear wavefunctions and account for the electron-nuclear correlation beyond the Born-Oppenheimer level. It is proposed that these terms can be incorporated using an optimized local effective potential.

I. INTRODUCTION

The Born Oppenheimer (BO) [1,2] or adiabatic [3] separation of the electronic and nuclear motion forms the basis of almost any quantum mechanical study of molecules and solids.

The method is based on the large difference between the electronic and nuclear masses, which implies that the light electrons are able to adapt almost instantaneously to the configuration of the much heavier nuclei. Consider a molecule with N_e electrons and N nuclei with masses M_α and charges Z_α and denote by r the set of electronic coordinates $r = \mathbf{r}_1 \dots \mathbf{r}_{N_e}$ and by R the set of nuclear coordinates $R = \mathbf{R}_1, \dots \mathbf{R}_N$.

The separation is effected by decomposing the complete molecular wavefunction, $\Psi_{\text{mol}}(r, R)$, in terms of a product of an electronic wavefunction depending parametrically on the nuclear positions and a nuclear wavefunction:

$$\Psi_{\text{mol}}(r, R) \simeq \Phi_R^{\text{BO}}(r) X^{\text{BO}}(R). \quad (1)$$

Since the electrons, more or less, cannot see the nuclear motion, the electronic wavefunction is chosen to be an eigenfunction of an electronic Hamiltonian derived from the molecular one by ignoring the nuclear kinetic energy or, equivalently, the nuclear mass is set to infinity. Finally, following Longuet-Higgins [3] and Messiah [4], the equation for the nuclear wavefunction can be obtained variationally. Keeping the electronic wavefunction fixed, one requires that the expectation value of the molecular Hamiltonian in terms of the adiabatic product wavefunction remains stationary when the nuclear wavefunction is varied. In the resulting effective nuclear Hamiltonian, in the absence of electronic degeneracies, the nuclei lie in a potential which, to high accuracy, coincides with the electronic energy eigenvalue. Each electronic level allows for a set of nuclear vibrational and rotational excitations but does not couple directly to any nuclear state of this set. For many physical systems and phenomena this separation is extremely successful, at least whenever degeneracy or near degeneracy of the electronic Hamiltonian is not involved. There are however other phenomena, which crucially depend on the coupling between the electronic and the nuclear wavefunctions. For these phenomena the adiabatic or BO approximation breaks down.

One should be careful about the variational derivation of the nuclear BO equation, because the ground state of a free molecule is a continuum state (since the complete molecular Hamiltonian is translationally invariant). Rigorously then, one should first separate off the

centre of mass of the molecule and then perform the adiabatic decomposition of the resulting bound wavefunction [5]. This leads to complicated terms in the resulting Hamiltonian. In this paper we do not separate off the centre of mass first, because our main aim is to show how one may improve upon the BO scheme, keeping at the same time the formulae simple and transparent, rather than maintaining complete rigour. One may justify the approach by imposing a confining potential that bounds the molecule within a very large but finite volume.

In probability theory, the joint probability distribution $p(r, R)$ of two sets of variables r, R can be factorized as the product $p(r, R) = p(r|R) p(R)$ of a conditional probability distribution $p(r|R)$ for the (electronic) variables r given R , times a marginal probability distribution $p(R)$ for the (nuclear) variables R . Hunter, proposed accordingly that the molecular wavefunction $\Psi_{\text{mol}}(r, R)$, i.e., the joint probability density amplitude of electronic and nuclear degrees of freedom could also be decomposed exactly as a product of a conditional probability amplitude $\Phi_R(r)$ of electronic variables, given fixed values for the nuclear variables times a marginal probability amplitude $X(R)$ for the nuclear degrees of freedom [6]:

$$\Psi_{\text{mol}}(r, R) = \Phi_R(r) X(R). \quad (2)$$

The BO electronic and nuclear wavefunctions $\Phi_R^{\text{BO}}(r)$, $X^{\text{BO}}(R)$ provide excellent approximations for $\Phi_R(r)$ and $X(R)$ but Hunter suggested that for each $\Psi_{\text{mol}}(r, R)$ one may find a conditional and a marginal probability density amplitudes, such that the factorization is exact. Czub and Wolniewicz discovered that for diatomic molecules, $X(R)$ is a nodeless wavefunction and hence the nuclear non-adiabatic potential must necessarily demonstrate spikes at the points where the adiabatic wavefunction has nodes [7]. Hunter observed that this result is more general [8,9]. The proof is straightforward: Take a molecular wavefunction that is to a good approximation given by a single BO product, $\Psi_{\text{mol}}(r, R) = \Phi_{1,R}^{\text{BO}}(r) X^{\text{BO}}(R)$, with the electronic part in the ground state and the nuclear wavefunction in an excited state with a node at R_0 . Since the electronic adiabatic states form a complete set, the molecular wavefunction can be expanded exactly in the series.

$$\Psi_{\text{mol}}(r, R) = \sum_n \Phi_{n,R}^{\text{BO}}(r) X_n(R). \quad (3)$$

Consequently, the diagonal of the nuclear N -body density matrix is equal to

$$\langle \Psi_{\text{mol}}(R) | \Psi_{\text{mol}}(R) \rangle = \sum_n |X_n(R)|^2. \quad (4)$$

Here and in the following, integration over all electronic degrees of freedom is denoted by the bra-ket symbols, while integration over the nuclear degrees of freedom is written as $\int d^{3N}R$. In order for $\langle \Psi_{\text{mol}}(R) | \Psi_{\text{mol}}(R) \rangle$ to have a node at R_0 , all vibrational states $X_n(R)$ must have a node at the same R_0 , which cannot happen. As an interesting aside, we note that Hunter's argument fails for nodes dictated by the symmetry. For example for identical fermionic nuclei, the molecular wavefunction must be antisymmetric with respect to exchange of two nuclei, say at positions $\mathbf{R}_1, \mathbf{R}_2$ and then the diagonal N -body nuclear density matrix and consequently the marginal probability amplitude must have nodes at $(\mathbf{R}_1, \mathbf{R}_2) = (\mathbf{R}, \mathbf{R})$.

So far, the impact of the work on the exact factorization of the molecular wavefunction has been limited and these ideas have not led to new practical ways to improve upon the adiabatic approximation. Perhaps in the early papers, attention focused too heavily on the nodeless character of the marginal probability density amplitude, which admittedly is a non-adiabatic coupling but probably not a very important one, since when the BO approximation is accurate, the correction does not have a measurably significant effect and when the BO approximation breaks down, it is not due to the nodeless property of the wavefunction. More importantly and rather curiously, the non-adiabatic equation determining the electronic wavefunction $\Phi_R(r)$ was never given. Knowledge of that equation would inform us of the non-adiabatic terms that correct the BO electronic wavefunction and hopefully accurate approximate treatments of these terms would emerge. This is the goal of our paper.

There is a representability issue which perhaps was not addressed adequately, namely, it is not clear whether the marginal probability distribution always corresponds to a meaningful nuclear wavefunction. For example the decomposition that was proposed to demonstrate the factorization (2) with $\Phi_R(r) = \Psi_{\text{mol}}(r, R) / \sqrt{\langle \Psi_{\text{mol}}(R) | \Psi_{\text{mol}}(R) \rangle}$ and $X(R) = \sqrt{\langle \Psi_{\text{mol}}(R) | \Psi_{\text{mol}}(R) \rangle}$

implies that the nuclear wavefunction is always bosonic even when the nuclei are fermionic. This problem can be overcome by introducing an R -dependent phase and writing

$$\Phi_R(r) = \frac{|\langle g|\Psi_{\text{mol}}(R)\rangle|}{\langle g|\Psi_{\text{mol}}(R)\rangle} \frac{\Psi_{\text{mol}}(r, R)}{\sqrt{\langle \Psi_{\text{mol}}(R)|\Psi_{\text{mol}}(R)\rangle}} \quad (5)$$

$$X(R) = \frac{\langle g|\Psi_{\text{mol}}(R)\rangle}{|\langle g|\Psi_{\text{mol}}(R)\rangle|} \sqrt{\langle \Psi_{\text{mol}}(R)|\Psi_{\text{mol}}(R)\rangle}, \quad (6)$$

where $g(r)$ is a suitably chosen electronic wavefunction that does not depend on R . In this way, the electronic wavefunction $\Phi_R(r)$ (conditional probability amplitude) depends on R and for identical nuclei is symmetric with respect to nuclear exchange. The nuclear wavefunction $X(R)$ (marginal probability amplitude) has the same symmetry properties as $\Psi_{\text{mol}}(r, R)$ with respect to nuclear exchange.

Adopting the small potential mentioned earlier to confine the molecule in a very large volume, the molecular, electronic and nuclear wavefunctions are all normalized to unity for convenience:

$$\int d^{3N}R \langle \Psi_{\text{mol}}(R)|\Psi_{\text{mol}}(R)\rangle = 1, \quad (7)$$

$$\langle \Phi_R|\Phi_R\rangle = 1, \quad (8)$$

$$\int d^{3N}R |X(R)|^2 = 1. \quad (9)$$

The electronic and nuclear wavefunctions have the freedom of an R -dependent phase (which, for identical nuclei must be symmetric with respect to exchange)

$$\Phi_R(r) \rightarrow e^{i\theta(R)} \Phi_R(r), \quad X(R) \rightarrow e^{-i\theta(R)} X(R) \quad (10)$$

since this transformation leaves $\Psi_{\text{mol}}(r, R)$ invariant. Apart from this freedom of phase the components X and Φ_R are unique.

II. NON-ADIABATIC ELECTRONIC AND NUCLEAR EQUATIONS

As the parametric product ansatz (2) does not constitute an approximation, it should be possible to improve significantly upon the BO level of accuracy, still using a product wave-

function (2), if we optimize the electronic wavefunction variationally, under the normalisation constraint (8), rather than choose it a priori to be an eigenstate of the BO electronic Hamiltonian. Naturally, we expect that in the non-adiabatic scheme, the electronic wavefunction will be coupled to the nuclear state.

The molecular Hamiltonian has the form:

$$H_{\text{mol}} = H_R^{\text{BO}} - \sum_{\alpha=1}^N \frac{\hbar^2 \nabla_{\alpha}^2}{2M_{\alpha}} \quad (11)$$

where ∇_{α}^2 is the Laplacian with respect to $\mathbf{R}_{\alpha}$ and H_R^{BO} is the electronic Hamiltonian:

$$H_R^{\text{BO}} = -\frac{\hbar^2}{2m} \sum_{j=1}^{N_e} \nabla_{\mathbf{r}_j}^2 + \frac{1}{2} \sum_{\substack{i,j=1 \\ i \neq j}}^{N_e} \frac{1}{r_{ij}} - \sum_{j=1}^{N_e} \sum_{\alpha=1}^N \frac{Z_{\alpha}}{|\mathbf{r}_j - \mathbf{R}_{\alpha}|} + \frac{1}{2} \sum_{\substack{\alpha,\beta=1 \\ \alpha \neq \beta}}^N \frac{Z_{\alpha} Z_{\beta}}{R_{\alpha\beta}}. \quad (12)$$

The nuclear Coulomb energy (last term) is independent of r and represents a constant shift of the electronic energy.

In order to obtain the equations determining the electronic and the nuclear wavefunctions, $\Phi_R(r)$ and $X(R)$, we have to vary the expectation value of the Hamiltonian H_{mol} with respect to $\Phi_R(r)$ and $X(R)$, under the normalisation constraints (8, 9). The latter are incorporated through the use of Lagrangian multipliers $\Lambda'(R)$, E . Note we have infinitely many constraints for the normalisation of the electronic wavefunction, one for each R , and we need as many Lagrangian multipliers $\Lambda'(R)$:

$$- \int d^{3N}R \Lambda'(R) (\langle \Phi_R | \Phi_R \rangle - 1), \quad (13)$$

$$-E \int d^{3N}R (|X(R)|^2 - 1). \quad (14)$$

A few words about notation: If the gradient operator ∇_{α} , or the Laplacian ∇_{α}^2 lies within parentheses or between bra-kets, as in $\langle \Phi_R | \nabla_{\alpha} \Phi_R \rangle$, it is implied that it acts only inside the bra-ket or parentheses. Note that when we use *square brackets*, as in $[-i\hbar \nabla_{\alpha} \pm \mathbf{A}_{\alpha}]$, the action of ∇_{α} is not confined within the brackets. Direct optimization of the electronic and nuclear wavefunctions under the constraints (13, 14) yields the non-adiabatic equations:

$$\left[H_R^{\text{BO}} - \sum_{\alpha=1}^N \frac{\hbar^2 \nabla_{\alpha}^2}{2M_{\alpha}} + \sum_{\alpha} \frac{X^*(R) (-i\hbar \nabla_{\alpha} X(R))}{M_{\alpha} |X(R)|^2} \cdot (-i\hbar) \nabla_{\alpha} \right] \Phi_R(r) = \Lambda(R) \Phi_R(r) \quad (15)$$

$$\left[\sum_{\alpha=1}^N \frac{[-i\hbar\nabla_{\alpha} + \mathbf{A}_{\alpha}(R)]^2}{2M_{\alpha}} + \langle \Phi_R | H_R^{\text{BO}} | \Phi_R \rangle + \sum_{\alpha=1}^N \frac{\hbar^2 \langle \nabla_{\alpha} \Phi_R | \nabla_{\alpha} \Phi_R \rangle}{2M_{\alpha}} - \sum_{\alpha=1}^N \frac{A_{\alpha}(R)^2}{2M_{\alpha}} \right] X(R) = E X(R). \quad (16)$$

where $\Lambda(R) = \Lambda'(R)/|X(R)|^2$ and $\mathbf{A}_{\alpha}(R)$ is the vector-potential-like real quantity

$$\mathbf{A}_{\alpha}(R) = \langle \Phi_R | -i\hbar\nabla_{\alpha} \Phi_R \rangle. \quad (17)$$

To make further progress, we define an electronic energy as

$$\mathcal{E}(R) = \left\langle \Phi_R \left| H_R^{\text{BO}} + \sum_{\alpha=1}^N \frac{[-i\hbar\nabla_{\alpha} - \mathbf{A}_{\alpha}(R)]^2}{2M_{\alpha}} \right| \Phi_R \right\rangle \quad (18)$$

which, by Eq. (17), can be written as

$$\mathcal{E}(R) = \langle \Phi_R | H_R^{\text{BO}} | \Phi_R \rangle + \sum_{\alpha=1}^N \frac{\hbar^2 \langle \nabla_{\alpha} \Phi_R | \nabla_{\alpha} \Phi_R \rangle}{2M_{\alpha}} - \sum_{\alpha=1}^N \frac{A_{\alpha}(R)^2}{2M_{\alpha}}. \quad (19)$$

After some straight-forward algebra, Eqs. (15) and (16) can be expressed in terms of this electronic energy as

$$\left\{ H_R^{\text{BO}} + \sum_{\alpha=1}^N \frac{[-i\hbar\nabla_{\alpha} - \mathbf{A}_{\alpha}(R)]^2}{2M_{\alpha}} + \sum_{\alpha=1}^N \frac{1}{M_{\alpha}} \left[\frac{X^*(R) (-i\hbar\nabla_{\alpha} X(R))}{|X(R)|^2} + \mathbf{A}_{\alpha}(R) \right] \cdot \left[-i\hbar\nabla_{\alpha} - \mathbf{A}_{\alpha}(R) \right] \right\} \Phi_R(r) = \mathcal{E}(R) \Phi_R(r) \quad (20)$$

$$\left[\sum_{\alpha=1}^N \frac{[-i\hbar\nabla_{\alpha} + \mathbf{A}_{\alpha}(R)]^2}{2M_{\alpha}} + \mathcal{E}(R) \right] X(R) = E X(R). \quad (21)$$

While, from the numerical point of view, this form of the equations is clearly not advantageous, the new form reveals some other interesting aspects: First of all, Eqs (20) and (21) are manifestly form-invariant under the gauge transformation (10). In particular, the electronic energy (18) which appears as “eigenvalue” in (20), is gauge invariant. The third term on the left-hand side of Eq. (20), while essential for the coupling between X and Φ_R , does not contribute to the energy $\mathcal{E}(R)$, i.e., when Eq. (21) is multiplied from the left with $\Phi_R(r)^*$ and integrated over r , this term drops out. One may confirm directly that the solution of the non-adiabatic equations (15, 16) is exact by showing that if $\Phi_R(r)$ and $X(R)$ satisfy (15, 16) then their product will be an eigenstate of H_{mol} :

$$H_{\text{mol}}\Phi_R(r) X(R) = E \Phi_R(r) X(R). \quad (22)$$

If the phase of the electronic wavefunction $\Phi_R(r)$ depends on r only, and if the dependence on R is continuous and differentiable, then the vector potential $\mathbf{A}_\alpha(R)$ vanishes and (16) simplifies to

$$\left[-\sum_{\alpha=1}^N \frac{\hbar^2 \nabla_\alpha^2}{2M_\alpha} + \langle \Phi_R | H_R^{\text{BO}} | \Phi_R \rangle + \sum_{\alpha=1}^N \frac{\hbar^2 \langle \nabla_\alpha \Phi_R | \nabla_\alpha \Phi_R \rangle}{2M_\alpha} \right] X(R) = E X(R). \quad (23)$$

The algebraic structure of the non-adiabatic nuclear equations (16, 21, or 23), coincides with the nuclear equation one encounters in the adiabatic approximation. However, in the latter, the electronic wavefunction is the BO one, satisfying

$$H_R^{\text{BO}} \Phi_R^{\text{BO}}(r) = \mathcal{E}^{\text{BO}}(R) \Phi_R^{\text{BO}}(r), \quad (24)$$

with $\mathcal{E}^{\text{BO}}(R) = \langle \Phi_R^{\text{BO}} | H_R^{\text{BO}} | \Phi_R^{\text{BO}} \rangle$, while in the non-adiabatic nuclear equations (16, 21, or 23), the electronic wavefunction $\Phi_R(r)$ is the non-adiabatic one satisfying (15) or (20).

The variational derivation of Eq. (16) guarantees that even in the approximate adiabatic scheme, the lowest energy eigenvalue, denoted by E^{BO} , is rigorously an upper bound to the exact ground state energy of the system:

$$E < E^{\text{BO}} \quad (25)$$

since E is the minimum of the molecular Hamiltonian in a Hilbert space which is wider than the Hilbert space of the adiabatic states. The inequality holds even when the electronic non-adiabatic equation is derived in a constrained way, as in the following section on the Optimized Effective Potential Method treatment of the non-adiabatic terms. It is interesting to note that

$$\langle \Phi_R | H_R^{\text{BO}} | \Phi_R \rangle > \mathcal{E}^{\text{BO}}(R) \quad (26)$$

since $\mathcal{E}^{\text{BO}}(R)$ is, for each R , the minimum of the expectation value of H_R^{BO} .

A necessary consequence of (25) and (26) is that

$$\sum_{\alpha=1}^N \frac{\hbar^2}{2M_\alpha} \int d^3R |X(R)|^2 \left(\langle \nabla_\alpha \Phi_R | \nabla_\alpha \Phi_R \rangle - \langle \nabla_\alpha \Phi_R^{\text{BO}} | \nabla_\alpha \Phi_R^{\text{BO}} \rangle \right) < 0 \quad (27)$$

where $X(R)$ is the lowest non-adiabatic nuclear state. Observe that all terms in the inequality are nonnegative. The inequality indicates that “on average” for the non-adiabatic electronic state that corresponds to the lowest nuclear state $\langle \nabla_\alpha \Phi_R | \nabla_\alpha \Phi_R \rangle < \langle \nabla_\alpha \Phi_R^{\text{BO}} | \nabla_\alpha \Phi_R^{\text{BO}} \rangle$. So, Φ_R can be expected to change less rapidly than Φ_R^{BO} as a function of R . It is worthwhile to remember that when a nucleus samples a region of a degeneracy or an avoided crossing of electronic levels, the concept of the adiabatic surface loses its meaning and an indication is that the potential energy depends strongly on the nuclear position. Small changes in R result in large changes in the wavefunction and potential. A lot of effort has been invested in constructing a different basis in the space of (near) degenerate electronic wavefunctions with energies that would behave smoothly close to the (avoided) level crossing. A convenient choice is the diabatic basis [12], defined as the basis that diagonalises the off-diagonal matrix elements $\langle \Phi_{R,m} | \nabla_\alpha \Phi_{R,n} \rangle$ [12,13]. It is known however, that rigorously, such a basis does not exist in general [13,14]. The non-adiabatic electronic wavefunctions and energies may offer a physical solution to this problem. There are cases when the the vector-like-potentials $\mathbf{A}_\alpha$ cannot all be made to vanish (for example when adiabatic electronic levels become degenerate at a point R), leading to a pseudo-magnetic field in (16) and a geometric phase [10]. An interesting question is whether the geometric phase is a consequence of the approximate nature of the adiabatic approximation and consequently whether it would disappear in the exact non-adiabatic scheme. We believe the geometric phase remains in the non-adiabatic scheme, since the non-adiabatic corrections depend on the nuclear mass and vanish for $M \rightarrow \infty$, whereas the geometric phase is independent of the size of the nuclear mass. The geometric phase is then not an artefact of the adiabatic approximation but a result of the parametric decomposition (2) of the molecular wavefunction which, by itself, is not an approximation.

III. APPROXIMATIONS FOR THE ELECTRONIC NON-ADIABATIC STATES

The exact non-adiabatic electronic equation is naturally very hard to solve and one has to resort to approximation techniques. A perturbative treatment of the non-adiabatic terms in the electronic equation is straightforward to apply if we keep the nuclear wavefunction $X(R)$ fixed. However, when the non-adiabatic terms are large (which is the case of interest here), the expansion may converge very slowly, or not converge at all. Another method to deal with the non-adiabatic electronic equation, that seems particularly promising, is to seek for the local R -dependent potential $V_R(\mathbf{r})$ that best approximates the effect of the non-adiabatic terms in (15), in a manner analogous to the Optimised Effective Potential (OEP) method [15–17].

Remember that the non-adiabatic equation was derived under the constraint of normalisation of the electronic wavefunction (8). This was the most general way of requiring that the electronic wavefunction depends parametrically on the nuclear positions. A more restrictive but perhaps more physical way is to impose that the electronic wavefunction must be an eigenstate of a Hamiltonian which is the sum of H_R^{BO} and an electronic potential V_R that depends on the nuclear positions. The variationally best potential is determined by making the expectation value of the molecular Hamiltonian (11) stationary. The optimal V_R will in general be an electronic N_e -body potential. A further approximation, to make the problem tractable, is to restrict to (local) one-body potentials. Hence we optimize the electronic wavefunction $\Phi_R(r)$ under the condition that it satisfies the equation

$$\left[H_R^{\text{BO}} + \sum_{j=1}^{N_e} V_R(\mathbf{r}_j) \right] \Phi_R(r) = E(R) \Phi_R(r). \quad (28)$$

In this way, the expectation value of the molecular Hamiltonian (11) becomes a functional of the effective non-adiabatic potential, $\langle H_{\text{mol}} \rangle = E[V_R]$.

Varying the effective potential, we obtain the functional derivative of $E[V_R]$ with respect to V_R :

$$\frac{1}{|X(R)|^2} \frac{\delta E[V_R]}{\delta V_R(\mathbf{r})} = \langle \Phi_R | \hat{\rho}(\mathbf{r}) \hat{G}_R \hat{V}_R | \Phi_R \rangle + \sum_{\alpha=1}^N \frac{\hbar^2}{2M_\alpha} \langle \Phi_R | \hat{\rho}(\mathbf{r}) \hat{G}_R | \nabla_\alpha^2 \Phi_R \rangle + \text{c.c.}$$

$$+ \sum_{\alpha=1}^N \frac{\hbar^2}{2M_\alpha} \frac{(\nabla_\alpha X(R))}{X(R)} \cdot \langle \Phi_R | \hat{\rho}(\mathbf{r}) \hat{G}_R | \nabla_\alpha \Phi_R \rangle + \text{c.c.} \quad (29)$$

where,

$$\hat{G}_R = \sum_n' \frac{|\Phi_{R,n}\rangle \langle \Phi_{R,n}|}{\mathcal{E}_n(R) - \mathcal{E}(R)}. \quad (30)$$

Summation is over all eigenfunctions of, $H_R^{\text{BO}} + V_R$, except Φ_R . For compactness, we use in (29,30) second-quantization notation, $\hat{\rho}(\mathbf{r})$ is the electron charge density operator and $\hat{V}_R = \int d^3\mathbf{x} V_R(\mathbf{x}) \hat{\rho}(\mathbf{x})$. Obviously, $\hat{G}_R |\Phi_R\rangle = 0$.

The optimized effective potential we seek corresponds to a stationary point of $E[V_R]$, i.e. the functional derivative vanishes

$$\frac{\delta E[V_R]}{\delta V_R(\mathbf{r})} = 0. \quad (31)$$

Solving the OEP equation (31) to obtain the potential can be very expensive. The approximation proposed by Krieger, Li and Iafrate [18,19] (KLI) can be used to simplify the equation considerably.

When the electronic state is a Slater determinant of Kohn-Sham spin-orbitals $\varphi_{R,\sigma}^j$, one obtains the spin-dependent KLI effective potential:

$$\begin{aligned} 2V_{R,\sigma}(\mathbf{r})\rho_\sigma(\mathbf{r}) &= 2 \int d\mathbf{r}' V_{R,\sigma}(\mathbf{r}') \sum_j |\varphi_{R,\sigma}^j(\mathbf{r})|^2 |\varphi_{R,\sigma}^j(\mathbf{r}')|^2 \\ &- \sum_\alpha \frac{\hbar^2}{2M_\alpha} \sum_j \varphi_{R,\sigma}^{j*}(\mathbf{r}) \nabla_\alpha^2 \varphi_{R,\sigma}^j(\mathbf{r}) + \sum_\alpha \frac{\hbar^2}{2M_\alpha} \sum_j |\varphi_{R,\sigma}^j(\mathbf{r})|^2 \langle \varphi_{R,\sigma}^j | \nabla_\alpha^2 \varphi_{R,\sigma}^j \rangle + \text{c.c.} \\ &- \sum_\alpha \frac{\hbar^2}{M_\alpha} \frac{(\nabla_\alpha X(R))}{X(R)} \cdot \sum_j [\varphi_{R,\sigma}^{j*}(\mathbf{r}) \nabla_\alpha \varphi_{R,\sigma}^j(\mathbf{r}) - |\varphi_{R,\sigma}^j(\mathbf{r})|^2 \langle \varphi_{R,\sigma}^j | \nabla_\alpha \varphi_{R,\sigma}^j \rangle] + \text{c.c.} \end{aligned} \quad (32)$$

This equation can be solved within the ordinary Kohn-Sham self-consistency loop: The potential $V_{R,\sigma}(\mathbf{r})$ to be used in the next iteration is obtained by plugging the Kohn-Sham orbitals and the $V_{R,\sigma}(\mathbf{r})$ of the previous iteration in the right-hand side of Eq. (32).

We have solved the non-adiabatic OEP equation for the simplest system that contains non-adiabatic couplings, namely the hydrogen ion H_2^+ . Using the BO scheme one obtains an excellent approximation for the ground state wavefunction, $\Psi(\mathbf{r}, \mathbf{R}) = \Phi_{\mathbf{R}}^{\text{BO}}(\mathbf{r}) X^{\text{BO}}(\mathbf{R})$.

To test our method, we used the inverse BO separation, i.e., we wrote, $\Psi(\mathbf{r}, \mathbf{R}) = \phi_{\mathbf{r}}^{\text{iBO}}(\mathbf{R}) \chi^{\text{iBO}}(\mathbf{r})$, where $\phi_{\mathbf{r}}^{\text{iBO}}(\mathbf{R})$ is the conditional probability density amplitude for the relative nuclear coordinate, when the electron is frozen at $\mathbf{r}$, and $\chi^{\text{iBO}}(\mathbf{r})$ the marginal probability density amplitude for the electron, moving in the potential surface of the nuclei. The inverse BO separation ignores terms of the order M/m and is hence very poor. Including the non-adiabatic correction terms (in this case the non-adiabatic terms can be transformed to have the form of a potential and hence the OEP method is exact), we found that the solution converged *numerically* to the correct wavefunction one obtains doing the BO separation in the orthodox way.

IV. SUMMARY

We have revisited the adiabatic/BO separation of the electronic and nuclear degrees of freedom in molecules, aiming to improve accuracy beyond the adiabatic level, but keeping at the same time the language and concepts of the adiabatic approximation which form the basis of almost all studies of molecular systems. We have derived a non-adiabatic correction for the electronic equation, which couples in a self-consistent way the electronic and nuclear wavefunctions. This correction has the form of an effective potential. The implementation of this correction to electronic structure codes that already use the OEP method to account for electronic exchange and correlation seems particularly promising.
